# Geoscience Australia Strategy 2028

## VISION

Geoscience Australia's science activities support the agency's role as the trusted source of information on Australia's geology and geography for government, industry and community decision-making

Relevant  
Science

Collaborative  
Science

Quality  
Science

Transparent  
Science

Communicated  
Science

Sustained  
Science

1. **Building Australia's resources wealth**
2. **Supporting Australia's community safety**
3. Securing Australia's water resources
4. **Managing Australia's marine jurisdictions**
5. Creating a location enabled Australia
6. Enabling an informed Australia

Pursuing  
Science  
Excellence

Making the  
most of our  
Data

Ensuring  
Supportive  
Stakeholders

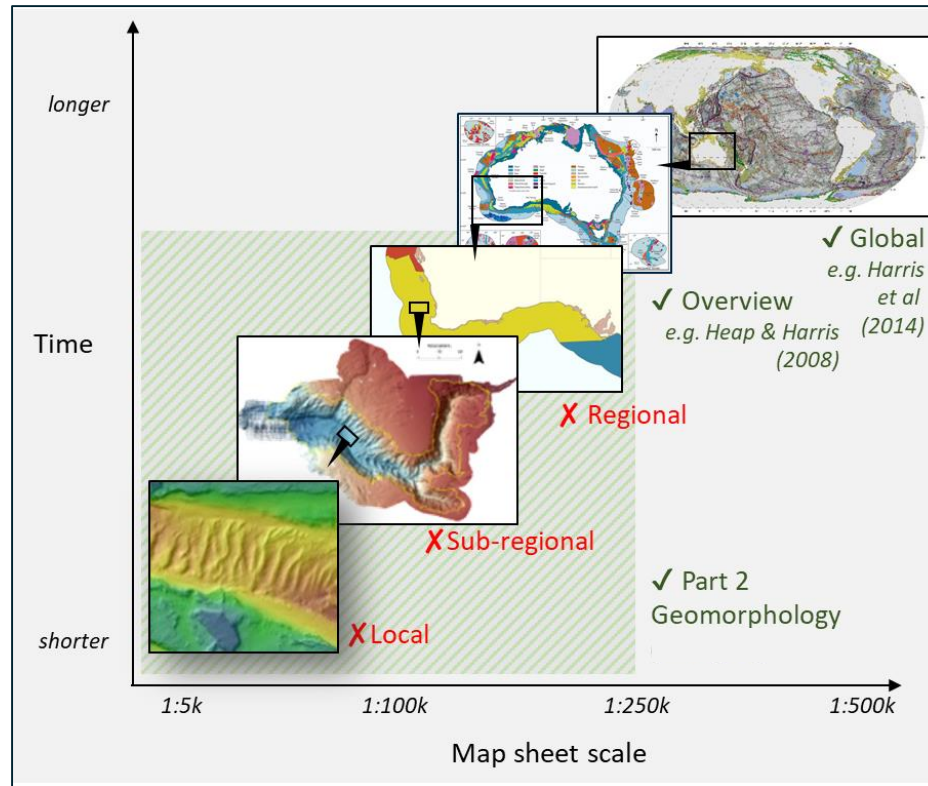

Enhancing  
Positive  
Organisational  
Culture

## Geoscience Australia Marine Strategy

1. Map and **understand** our seabed, to support growth of the Blue Economy to \$100b per year.
2. Coastal landform monitoring
3. Support legal and regulatory certainty for marine jurisdiction

Przeslawski et al (2023)

## Benefits of using a best practice

- Collaborative opportunities
- Efficient use of time
- Improved systems interoperability
- Data comparability and collatability
- Greater trust in data
- Streamlined regulatory approval
- Higher funding success

# Workshop participants (16 countries)

Part 1: Morphology

Step 1:  
map shapes  
& define  
Morphology

SEAMOUNT

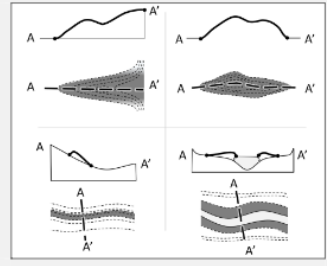

A prominent feature rising more than 1000 m above the surrounding relief (modified from IHO, 2019).

SEAMOUNTS are larger than KNOLLS and HILLS (<1000 m) and may incorporate PEAKS (and other features).

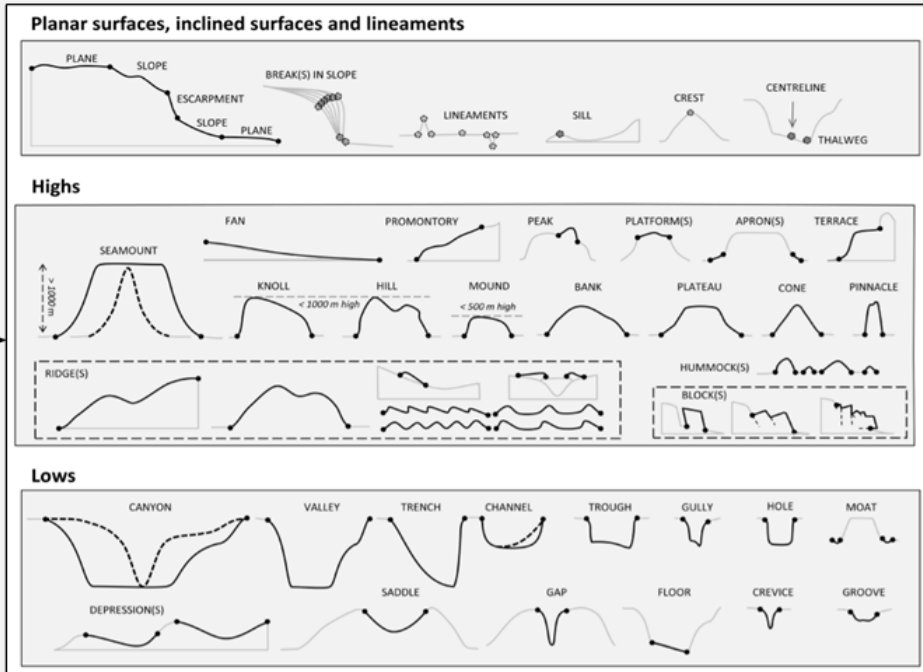

RIDGE

An elongated elevation of varying complexity, size and gradient (length > width) (modified from IHO, 2019).

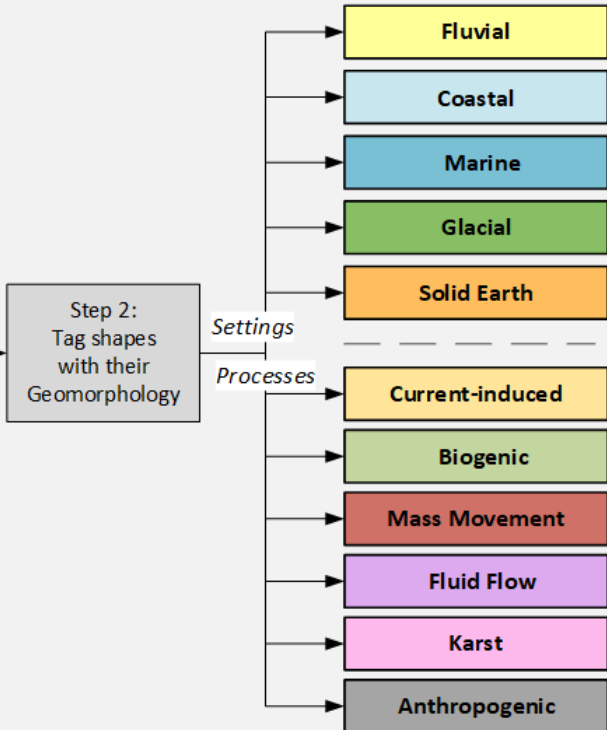

## Part 1: Morphology

| Setting / Process | BGU * | BGU-T *                        | Part 2 Geomorphology definition **                                                                                                                                                                                                                                         | Apps *** I – VI |
|-------------------|-------|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
|                   |       | ridge and runnel               | A low gradient sand bar and trough that forms alongshore in the intertidal zone of a BEACH. On macrotidal beaches, multiple ridges (CF. INTERTIDAL BARS) and runnels may form across the intertidal zone spanning tens to hundreds of metres (Masselein and Hughes, 2014). | V               |
|                   |       | washover bar                   | A low gradient sandy to gravelly deposit located on the landward side of a BARRIER deposited over a BACK-BARRIER FLAT or LANGOON facies, formed by storm surge or tsunami run-up. Typically fan shaped in plan view (Reineck and Singh, 2012).                             | III, IV, V      |
|                   |       | intertidal bar (aka. ridgebar) | A low gradient sand bar that forms in the intertidal zone of BEACHES. On macrotidal coasts, multiple bars typically form into a RIDGE AND RUNNEL system (Masselein and Hughes, 2014).                                                                                      | II, III, IV     |
|                   |       | tidal bar                      | Discontinuous COASTAL BARS that typically form in tide-dominated SUBERIAL CHANNELS, which are aligned to the dominant flow direction (Dalrymple et al., 1992).                                                                                                             | II, III, IV     |
|                   |       | barrier complex                | Amalgamated, shore-parallel sand bodies incorporating BEACH, coastal                                                                                                                                                                                                       |                 |

| Potential applications                           | Examples                                                                                                                                                                                              |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (I) to infer potential habitat                   | Ocean management, seafood industry, biodiversity, conservation (e.g. Harris and Baker, 2011).                                                                                                         |
| (II) seafloor stability assessment               | To assess landslide and tsunami risk (e.g. Bardet et al., 2003); develop GIS ground models for offshore renewables (e.g. Barwise et al., 2014); for safe navigation, infrastructure for hydrocarbons. |
| (III) sediment modelling                         | To infer near seafloor energy, sediment transport pathways, volumes / budgets (e.g. Stow et al., 2009).                                                                                               |
| (IV) climate and past environment reconstruction | For studies of modern climate change, palaeoenvironmental reconstruction, archaeology (e.g. Brooke et al., 2017; O’Leary et al., 2020).                                                               |
| (V) coastal and marine management                | To investigate environmental, erosion, seafood industry, recreational fishing, administrative borders.                                                                                                |
| (VI) mineral resources assessment                | To locate fluvial and coastal placer deposits (Kudrass, 2017) and aggregates.                                                                                                                         |

18 Index of terms

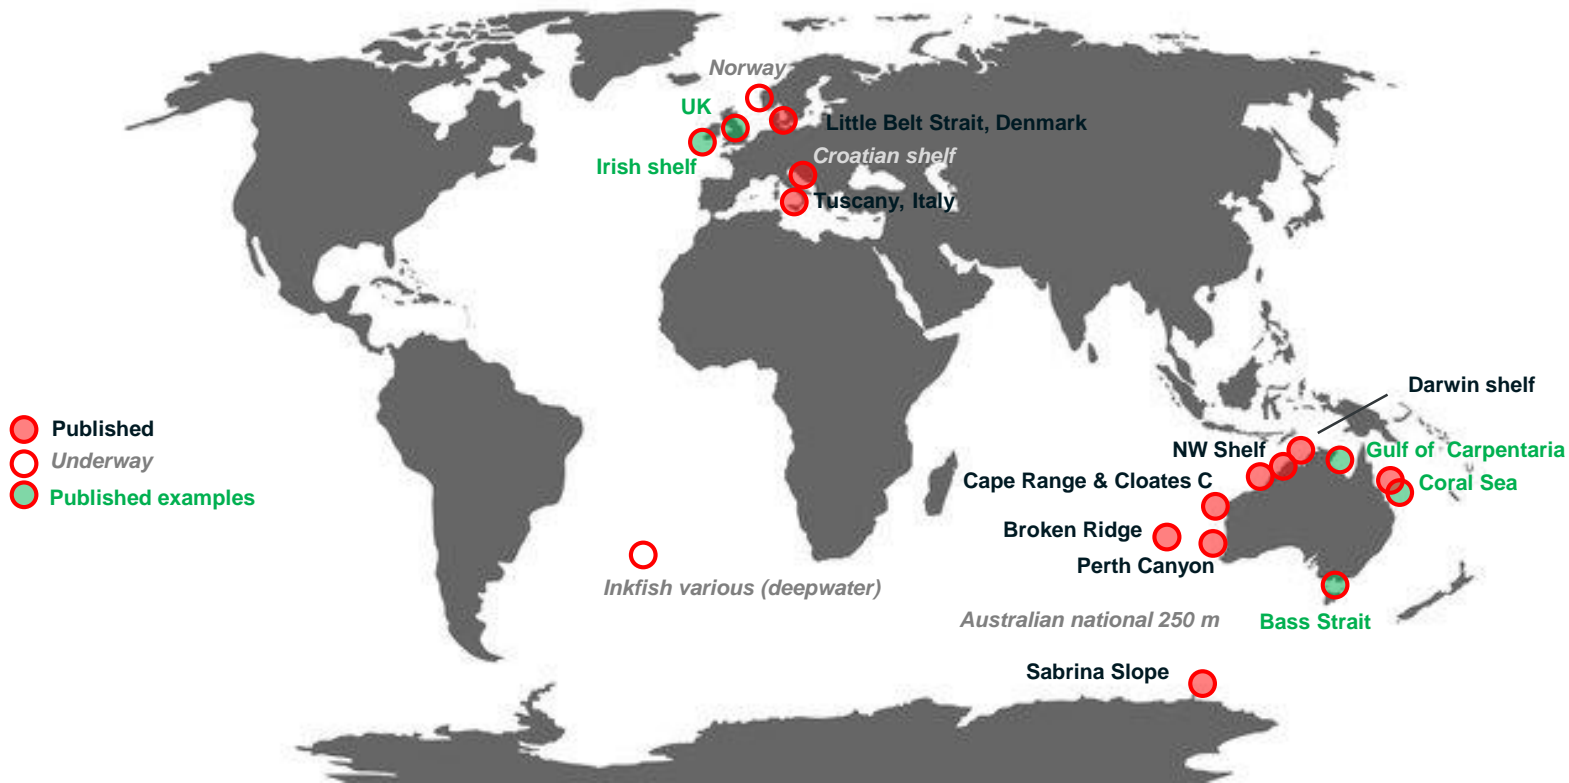

The following list of terms is provided to assist the user in finding which Setting / Process chapter each term is classified. BGU-T marked with an asterisk are not defined in the glossary.

|                           |                       |       |
|---------------------------|-----------------------|-------|

# Products based on the scheme (to October 2023)

INFOMAR Programme: more than 85% seabed mapped at high resolution.

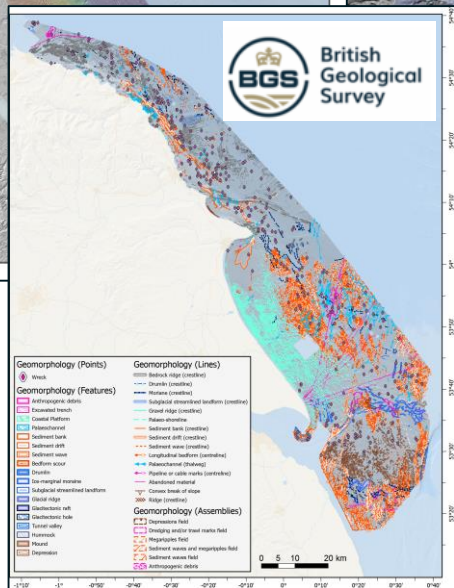

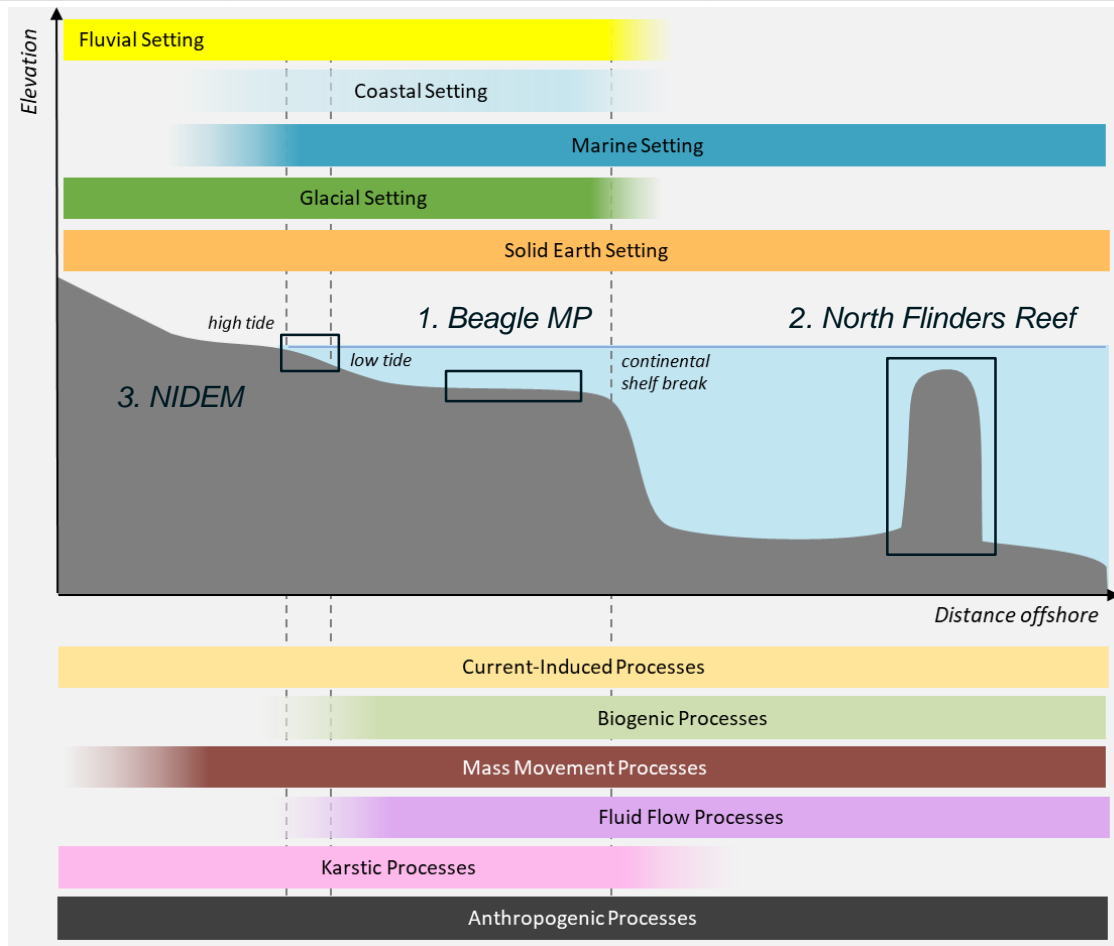

- includes 33 different geomorphic units and 3 substrate types;
- adopted the **MIM-GA (two-part) classification scheme**;

# IHO-based classifications

IHO B-6 (2019)

Two-part scheme (2020, 2022)

Cookbook (2022)

## I. GENERIC TERMS

**NOTE:** Only the generic terms in this section should be used in any new undersea feature name proposal that is intended for submission to SCUFN.

### ABYSSAL PLAIN

An extensive, flat or gently sloping region, usually found at depths greater than 4000 m.

### APRON

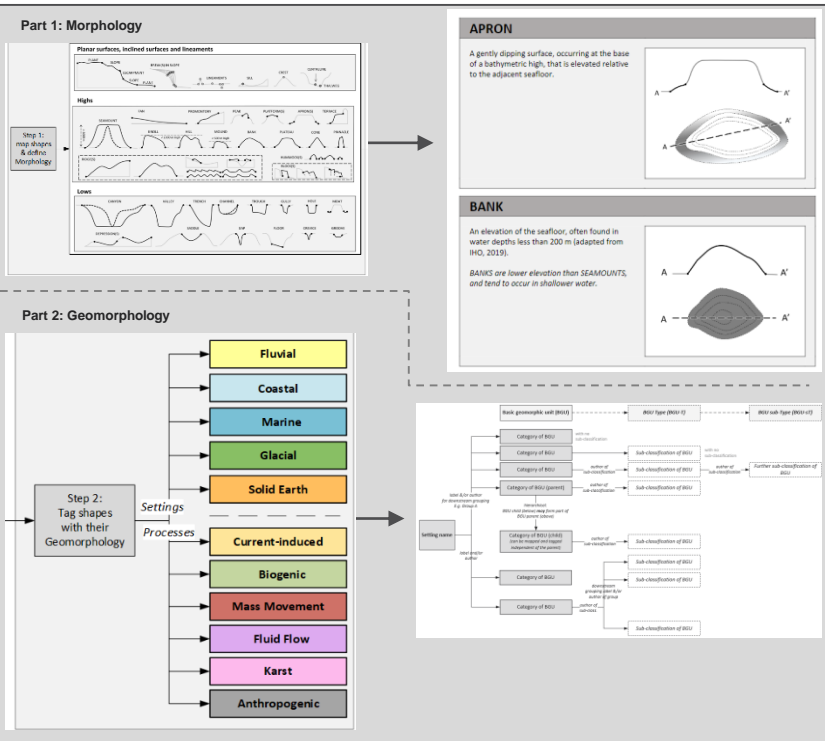

A gently dipping SLOPE, with a smooth surface, commonly found around groups of islands and SEAMOUNTS.

### BANK

An elevation of the seafloor, at depths generally less than 200 m, but sufficient for safe surface navigation, commonly found on the continental shelf or near an island.

### BASIN

A depression more or less equidimensional in plan and of variable extent.

### ABYSSAL PLAIN

**Definition:** An extensive, flat or gently sloping region, usually found at depths greater than 4000 m.

**Dimensions:** Generally greater than 100 x 100 km.

**Length-to-width ratio:** Typically, about 1:1, but can be elongate up to 3:1.

**Depth:** Usually greater than 4000 m

**Steepness:** Usually less than 1 degree – which is 175 m change in elevation over 10 kilometres (km).

**Comments:** These are deep-sea features and should not be confused with BASINS that can also occur at shallower depths. ABYSSAL PLAINS differ from BASINS in that they are part of the deep ocean floor, sometimes extending around isolated SEAMOUNTS and RIDGES, and often have little or no sediment cover. The edges of ABYSSAL PLAINS can be difficult to define as they tend to merge with the SLOPE at continental margins.

**Similar Features:** If length to width ratio is greater than 3:1 consider TROUGH or TRENCH definitions. If smaller than 100 x 100 km consider BASIN, DEEP and HOLE definitions.

### APRON

**Definition:** A gently dipping SLOPE, with a smooth surface, commonly found around groups of islands and SEAMOUNTS.

**Dimensions:** Can vary greatly from less than one km<sup>2</sup> to 100s of square kilometres.

**Length to width ratio:** Typically, about 1:1, but can be elongate up to 3:1.

**Depth:** Any water depth.

**Steepness:** Usually less than 1 degree - 175 m change in elevation over 10 kilometres.

**Comments:** There are few of these in the gazetteer.

**Similar Features:** If not associated with a SEAMOUNT consider FAN definition. If steeper than two degrees consider SLOPE definition.

# IHO-based classifications

| Term         | β6                                                                                                    | Two-part scheme def                                                                                                                              | Morph (Part 1) or Geomorphology (Part 2)? | Cookbook                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
